Statistics:

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

                                                                                                                                                             This polypepide comprises the hepatitis B virus (HBV) 25 kDa (p25) protein that is encoded by the full-length HBV precore gene. Evidence is provided that HBV replication is inhibited in the presence of high levels of HBV precore or precore-related proteins. These proteins can be incorporated into HBV nucleocapsids along with the p21 core protein (see W50251), which is the usual nucleocapsid component, and thereby render the nucleocapsids of the precore proteins, or certain variants of them, capression of the precore proteins, or certain variants of them, eagression of the precore proteins, or certain variants of them, inhibitory proteins include p25, p22 (see W50241), Met-p22 (see W50242), p18 (see W50236), Met-p18 (see W50237) and Met-p18-Het recombinant methods using claimed expression vectors and host cells. They can be provided expension vectors and host cells. They can be provided expension vectors and host construct that directs overexpression of an inhibitory protein in target cells is used for the gene therapy of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Query Match

                                                                                     DR N-ESDB; (29105.)

PY Vaccine comprises recombinant, attenuated pox-virus - use for year vaccinating against viral infections such as rables, hepatitis B, PT HIV, HSV, EBV, CMV, mumps etc.

PS Disclosure; Fig 13; 456pp; English.

The sequence given is encoded by an expression cassette which comprises a portion of the hepatitis B virus (HBV) pre-S region (S12/CC comprises a portion of the hepatitis B virus (HBV) pre-S region (S12/CC core) which is precisely linked to the I3L promoter derived from CC vaccinia virus. This DNA sequence was linked to the S1 and S2 core) which is precisely linked to the I3L promoter derived from CC sequences and this fragment was used in the construction of a NYVAC recombinant expressing the HBV gene. Other HBV genes were also used in the construction. These were HBV M protein (small pre-S antigen, spsAg) and HBV L (large pre-S antigen, 1psAg). Each of these gene sequences were inserted individually into three different sites of CC vaccinia virus which has been modified by deletion of six non-essential regions of the genome encoding known or potential virulence factors. The deletion loci were engineered as recipient loci for the insertion of the thetae inserted sequences ensured consecuria genome and would cause unviable vaccinia virus. See also

New conjugates and fusion proteins of immunogenic polypepytide and hepatitis B core antigen and T cell stimulating polypeptide coresp. to core antigen, useful in vaccines.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Disclosure; p; English.

This sequence contains the T cell stimulating epitopes, amino acid residue 1-55 and 70-140. It is believed that the regions 1-44 and 70-140 do not contain determinants that suppress T cell activation. Polypeptides essentially consisting of 15 to 55 amino acids corresponding to the above mentioned HBV regions are T cell stimulating. Coupling a polypeptide immunogen to such sequences, e.g. by using a bifunctional reagent which forms a disulphide link, improves its immunogenicity. These are useful in vaccines and can be therapeutically to improve T cell response to HBCAg in infected

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       밁
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       PT DNA encoding proteins which can be incorporated with wild type proteins which can be incorporated with wild type protein submit(s) into a viral nucleocapsid - useful for protein this polypeptide comprises the hepatitis B virus Claim 9; Page 34-35; 60pp; English.

CC This polypeptide comprises the hepatitis B virus (HBV) 22 kDa (p22) crocein that is produced by elimination of the 19-amino acid leader certain that is produced by elimination of the 19-amino acid leader certain the 25 kDa full-length HBV precore protein (see W50250). Evidence is provided that HBV replication is inhibited in ct the presence of high levels of HBV precore or precore-related croce proteins. These proteins can be incorporated into HBV nucleocapsids component, and thereby render the nucleocapsids concleocapsid concleocapsid concleocapsid strip HBV pregenomic RNA. Thus, over-cappression of the precore proteins, or certain variants of them, cleaked to transdomanant inhibition of HBV replication. Suitable consistency proteins include p25 (see W50237), p22, Met-p22 (see W50242), p18 (see W50238), Met-p18 (see W502437) and Met-p18 HHet (see W50242), p18 (see W50238), Met-p18 (see W50244-49) may be consistent methods using claimed corporate and host cells. They can be provided exogenously continued that directs overcexpression contents of the protein in target cells is used for the gene contents of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Query Match

This is the 21 kDa (p21) protein of hepatitis B virus (HBV) that assembled into a 180 kSa subunit nucleocapsid Structure that promotes viral replication. Evidence is provided that HBV replication is inhibited in the presence of high levels of HBV precore or precore-related proteins. These proteins can be incorporated into HBV nucleocapsids along with the p21 core protein and thereby render the nucleocapsids deficient in encapsidating HBV pregenomic RNA. Thus, over-expression of the precore proteins or certain variants of them, leads to transdominant inhibition of HBV replication. Suitable inhibitory proteins include p25 (see w5023), p22 (see w50241), Met-p22 (see w50242), p18 (see w50235), Met-p18 (see w50237) and Met-p22 (see w50238). These proteins can be produced by recombinant methods using claimed expression vectors and host cells, and can be provided exogenously to target cells for use in inhibiting HBV replication. Alternatively, a nucleic acid construct that directs overexpression of an inhibitory protein in target cells is used for the gene therapy of HBV

The inhibitory effect is species-specific and is achieved by deletion of a few C-terminal amino acids from the core protein, and/or by joining the core protein to a hepadnavirus surface protein (see also W09045), creating a core-surface fusion. Such mutant polypeptides (see also W09046-50) can be used to treat hepadnavirus, e.g. HBV,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 09-JAN-1997.

                                                                                                   Recombinant DNA coding for polypeptide - have specificity of hepatitis B viral antigens in detection or antibody stimulation Example; Figs 3-4; 43pp; English. Human serum from a single HBSAg positive, HBBAg positive donor (serotype adym) was used to prep. a DNA-contg. pellet which was labelled with 3H or 32P as described by P. M. Kaplan et al (1973). The labelled DNA was then extracted with phenol from the resulting pellet using the procedure of L. I. Lutwick and W. S. Robinson (1977). It was then cloned in plasmid pBR322 which was used to transform E. coli. Micro-organisms prepd. by the processes are deposited at the NCIB as pBR322-HBV-G-L, e.g. E. coli HB101/pBR322-Pst I dG:
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Sequence of core antigen.
Hepatitis B virus; antigen;
Hepatitis B virus.

Plasmid phBv DN AA carries an Insert (T49598) coding for a protein (See also W99048) comprising a hepatitis B virus (HBV) core protein (see calso W99044) fused in-frame at amino acid 179 with the HBV surface protein (see also W09045) at amino acid a mino acid 175 to the C (T49599) expresses the HBV core fused at amino acid 175 to the Surface protein at amino acid 112 (W09049). pHBV DN AA was at C least as potent an inhibitor of HBV replication as construct C PHBV DN (T49597); pHBV DN BB was less inhibitory than pHBV DN. C Vectors expressing hepadnavirus dominant negative core mutants can be utilised in the gene therapy of viral infections.

Human serum from a single HBsAg positive, HBeAg positive donor (serotype adym) was used to prep. a DNA-cont, pellet which was labelled with 3H or 32p as described by P. M. Kaplan et al (1973). The labelled DNA was then extracted with phenol from the resulting pellet using the procedure of L. I. Lutwick and W. S. Robinson (1977). It was then cloned in plasmid pBR322 which was used to transform E. coli. Micro-organisms prepd. by the processes are deposited at the NCIB as pBR322-HBV-G-L, e.g. E. coli HBJO1/pBR322-Pst I dG: HBY-KPN I dC: Tetr AmpS HBV+.

Disclosure; Fig 7; 12pp; Japanese.
The hepatitis B core gene is recombined with PV-1 DNA and IL-1 beta to form a plasmid (Q47738) which is then used a vaccine. NB: Sequence is difficult to read in the original
                                                                                                                                                                                                 Recombinant plasmid for high immunogenity virus - contrecombined haemaggluttnin gene, hepatitis B core gene virus and exotic genes.

The hepatitis B core gene is recombined with pv-1 DNA and L-1 beta to form a plasmid (047738) which is then a vaccine. NB: Sequence is difficult to read in the or

Disclosure; Fig 3: 13pp; Japanese.

The sequence is that of hepatitis virus core antigen (HBCAg). It can be used as a vaccine for the prevention of infections by hepatitis B virus (HBV) and also in the diagnosis of early stages of HBV infection. See also P40310.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                             16-FEB-1994 (first entry)

The hepatitis B core gene is recombined with pv-1 DNA
and IL-1 beta to form a plasmid (Q47738) which is then used to produce
a vaccine. NB: Sequence is difficult to read in the original
specification.

MPsrch_pp protein - protein database search, using Smith-Waterman algorithm

Tabular output not generated. Run on: Thu Dec 16 13:00:27 1999; MasPar time 12.64 Seconds 786.145 Million cell updates/sec

Description: Perfect Score: Sequence: >US3835-1-38183 (1-248) from us3835-1-38183.pep 1854 1 MDIDPYKEFGATVELLSFLP......RRRRSQSPRRRRSQSRESQC 248

Scoring table: РАМ 150 Gap 11

Searched:

122810 seqs, 40068593 residues

Post-processing: Minimum Match 0% Listing first 45 summaries

Database:

pir60 1:pir1 2:pir2 3:pir3 4:pir4

Statistics: Mean 47.523; Variance 119.912; scale 0.396

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

Database:

swiss-prot37 1:swissprot

Statistics: Mean 48.750; Variance 106.745; scale 0.457

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
